Sequence Diagrams II

Object-orientation: Centralized vs Decentralized Control/Computation

Class Diagrams II

Layered Architecture

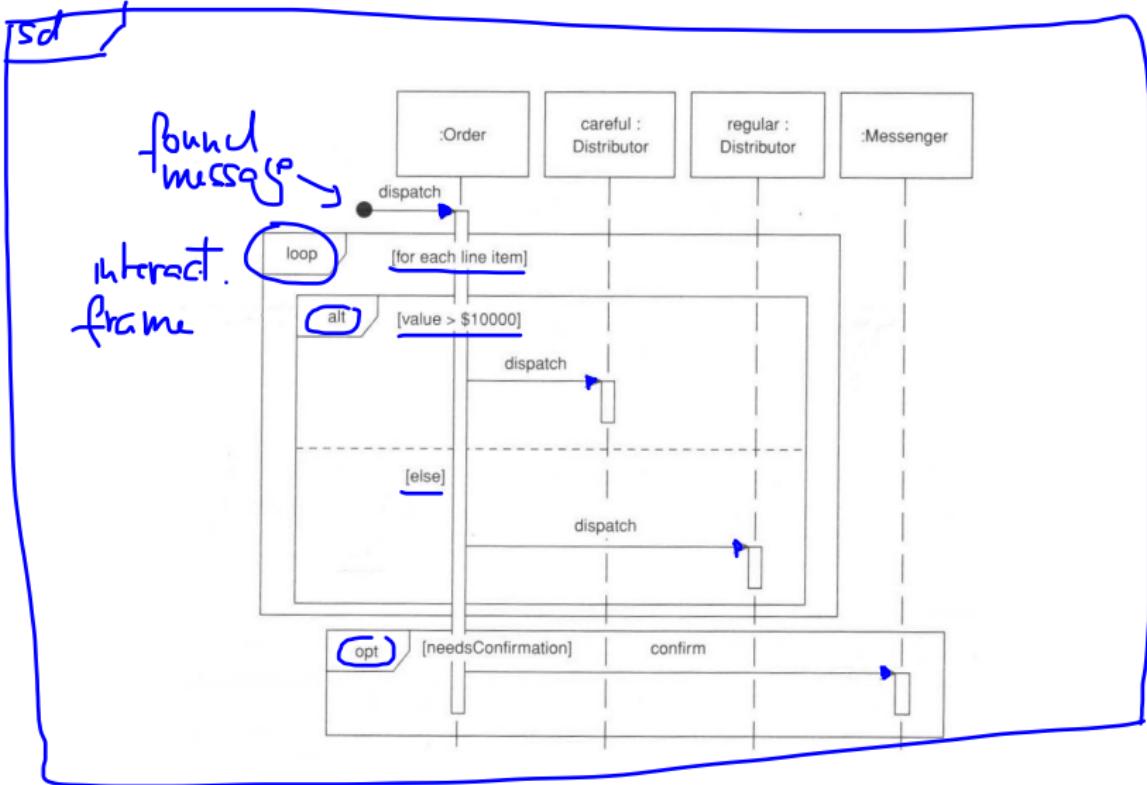

Interaction Frames Example

Realising an algorithm using a sequence diagram

```
public void dispatch() {  
    for (LineItem lineItem : lineItems) {  
        if (lineItem.getValue() > 10000) {  
            careful.dispatch();  
        } else {  
            regular.dispatch();  
        }  
    }  
    if (needsConfirmation()) {  
        messenger.confirm();  
    }  
}
```

interaction frames

Realisation with Interaction Frames

Interaction Frame Operators I

Operator	Meaning
alt	Alternative multiple fragments; only the one whose condition is true will execute (Figure 4.4).
opt	Optional; the fragment executes only if the supplied condition is true. Equivalent to an alt with only one trace (Figure 4.4).
par	Parallel; each fragment is run in parallel.
loop	Loop; the fragment may execute multiple times, and the guard indicates the basis of iteration (Figure 4.4).
region critical	Critical region; the fragment can have only one thread executing it at once.
neg	Negative; the fragment shows an invalid interaction.
ref	Reference; refers to an interaction defined on another diagram. The frame is drawn to cover the lifelines involved in the interaction. You can define parameters and a return value.
sd	Sequence diagram; used to <u>surround an entire sequence diagram</u> , if you wish.

Sequence Diagrams II

Object-orientation: Centralized vs Decentralized Control/Computation

Class Diagrams II

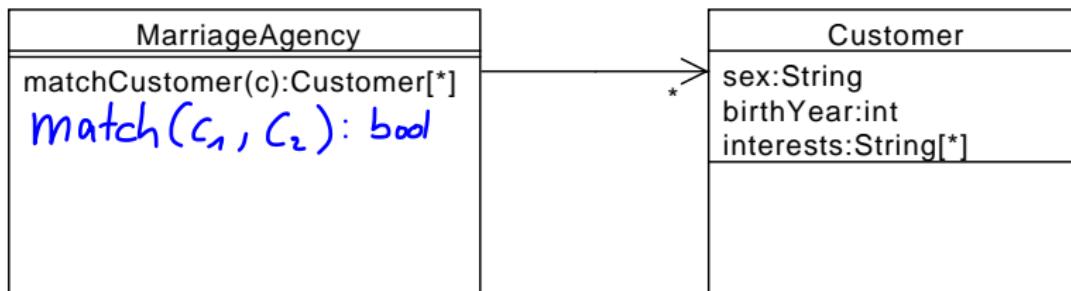

Layered Architecture

Marriage Agency: centralized control

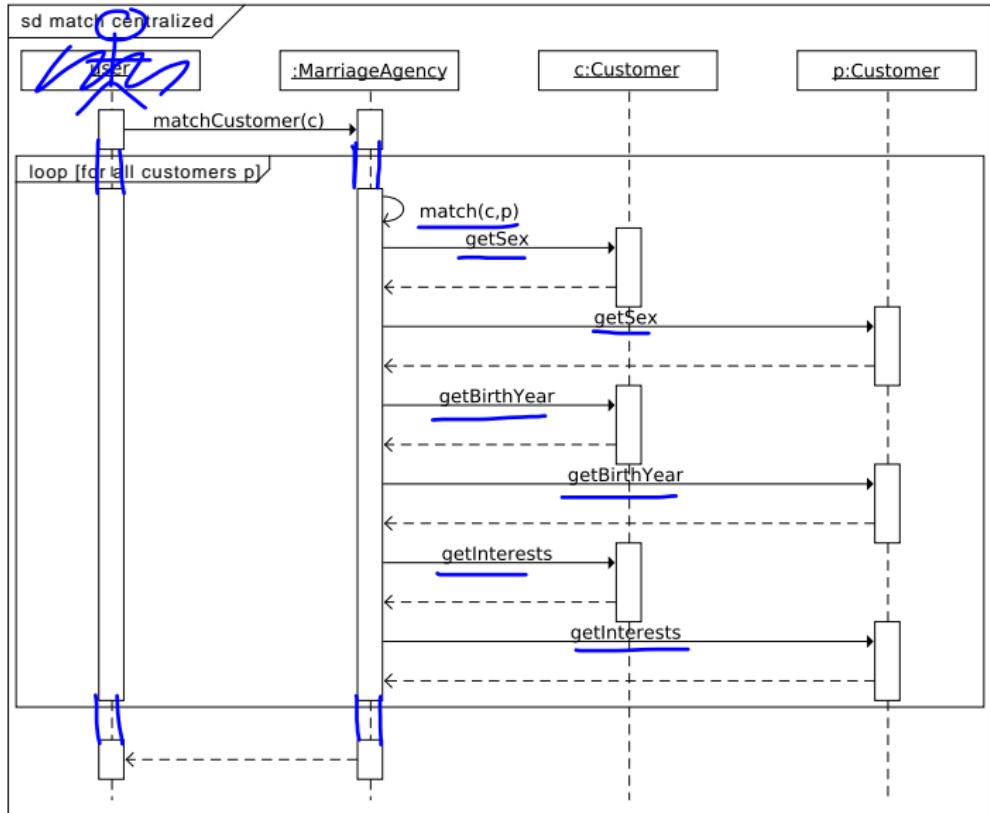

```
public class MarriageAgency{
    private List<Customer> customers = new ArrayList<Customer>();
    public List<Customer> matchCustomer(c) {
        List<Customer> matches = new ArrayList<Customer>();
        for (Customer candidate : customers) {
            → ... // if customer matches candidate add to variable matches
        }
        matches
        return matches;
    }
}
```

Marriage Agency: centralized control

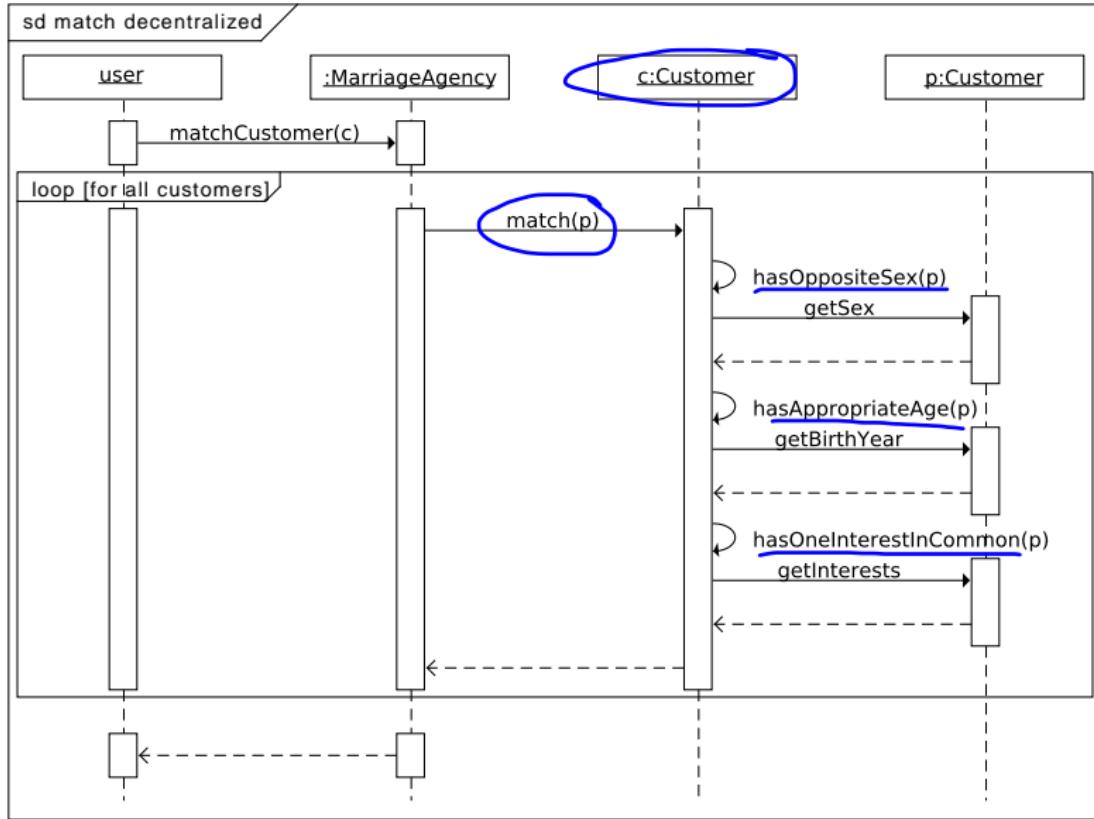

```
public class MarriageAgency{
    private List<Customer> customers = new ArrayList<Customer>();
    public List<Customer> matchCustomer(c) {
        List<Customer> matches = new ArrayList<Customer>();
        for (Customer candidate : customers) {
            // if customer matches candidate add to variable matches
            if [match(c, candidate)] {
                matches.add(candidate);
            }
        }
        return candidate;
    }
    public boolean match(Customer customer, Customer candidate) {
        ....
    }
}
```

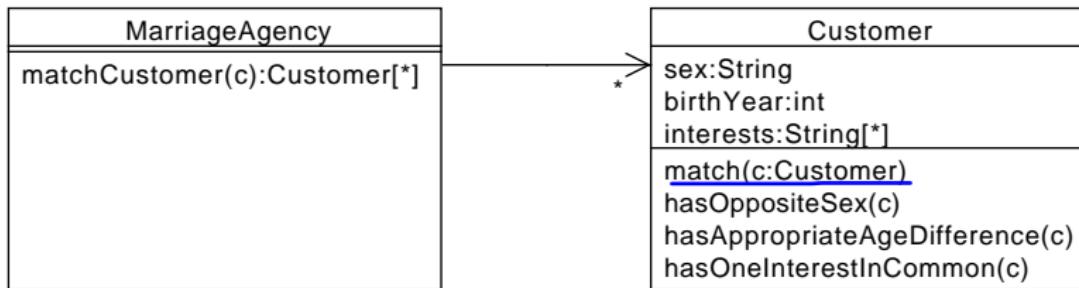

Marriage Agency: centralized control

Marriage Agency: decentralized/distributed control

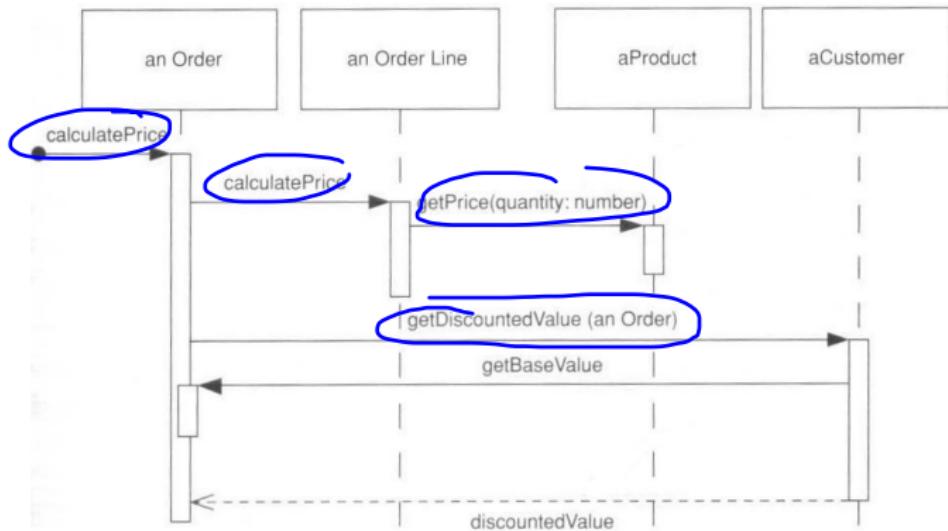

Marriage Agency: decentralized/distributed control

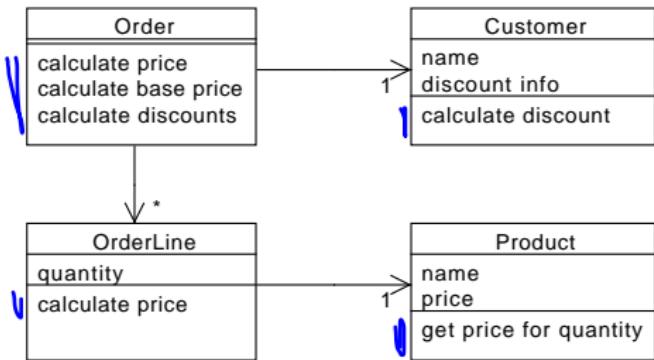

```
public class MarriageAgency{
    private List<Customer> customers = new ArrayList<Customer>();
    public List<Customer> matchCustomer(c) {
        List<Customer> matches = new ArrayList<Customer>();
        for (Customer candidate : customers) {
            if (c.match(candidate)) {
                matches.add(candidate);
            }
        }
        return candidate;
    }
}
public class Customer {
    ...
    public bool match(Customer candidate) {
        ....
    }
}
```

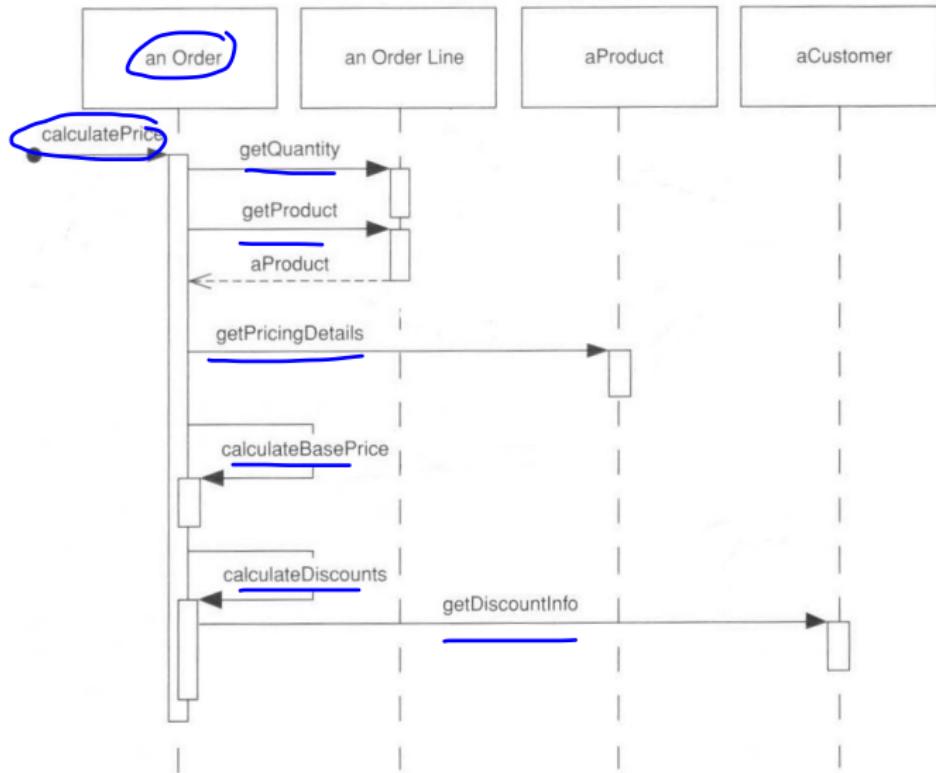

Distributed control

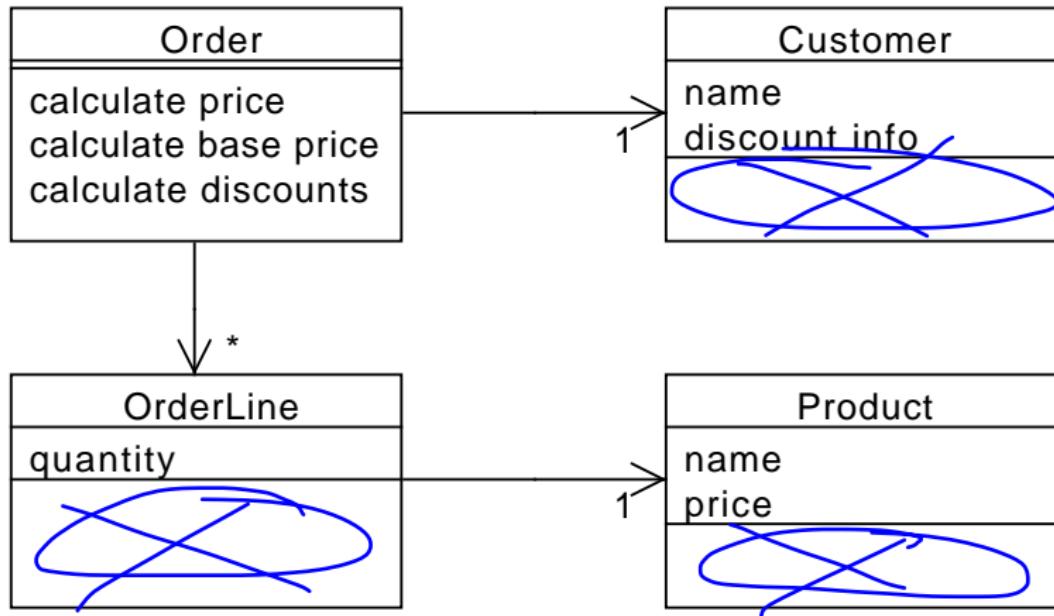

Distributed Control: Class diagram

Centralised control

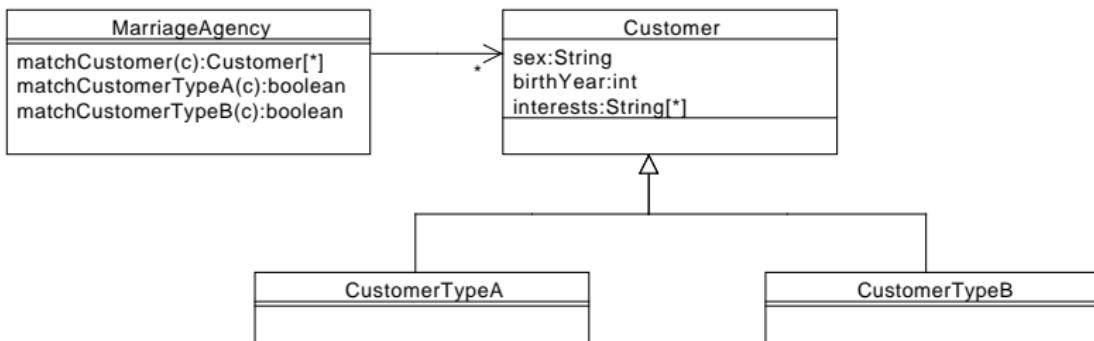

Centralized control

Centralized vs Distributed control

- ▶ Centralized control
 - ▶ **One method**
 - ▶ Data objects
 - procedural programming language
- ▶ Distributed control
 - ▶ Objects **collaborate**
 - ▶ Objects = data and behaviour
 - Object-orientation
- ▶ Advantage
 - ▶ Easy to adapt
 - Design for *change*

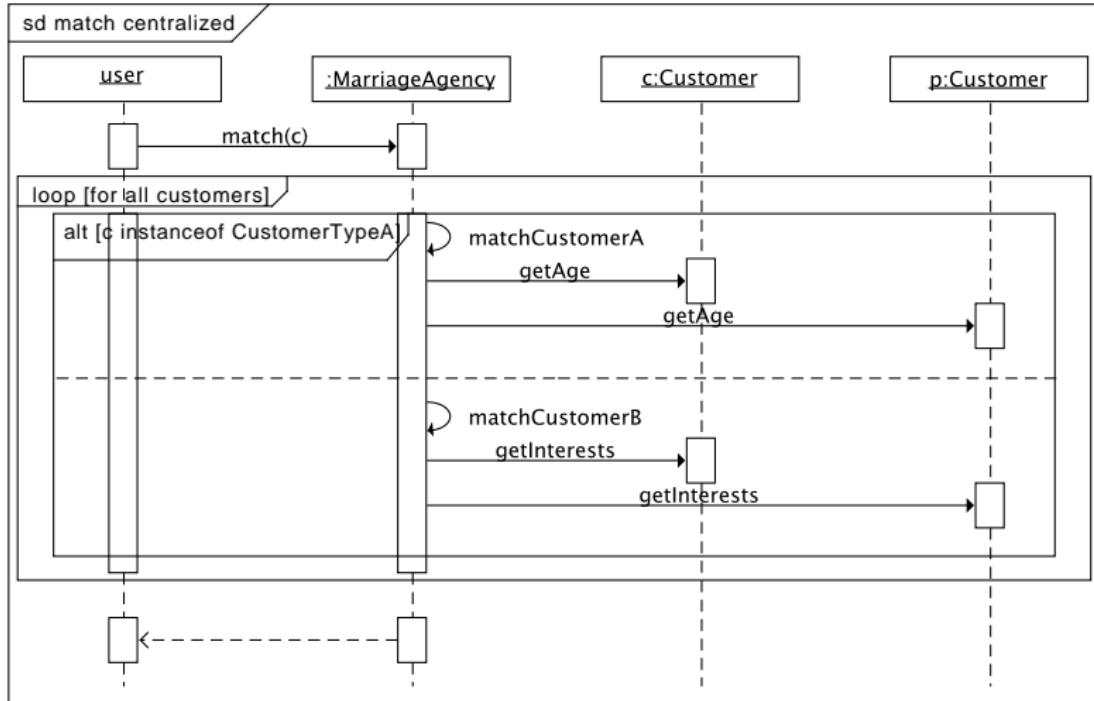

Design for change: centralized control

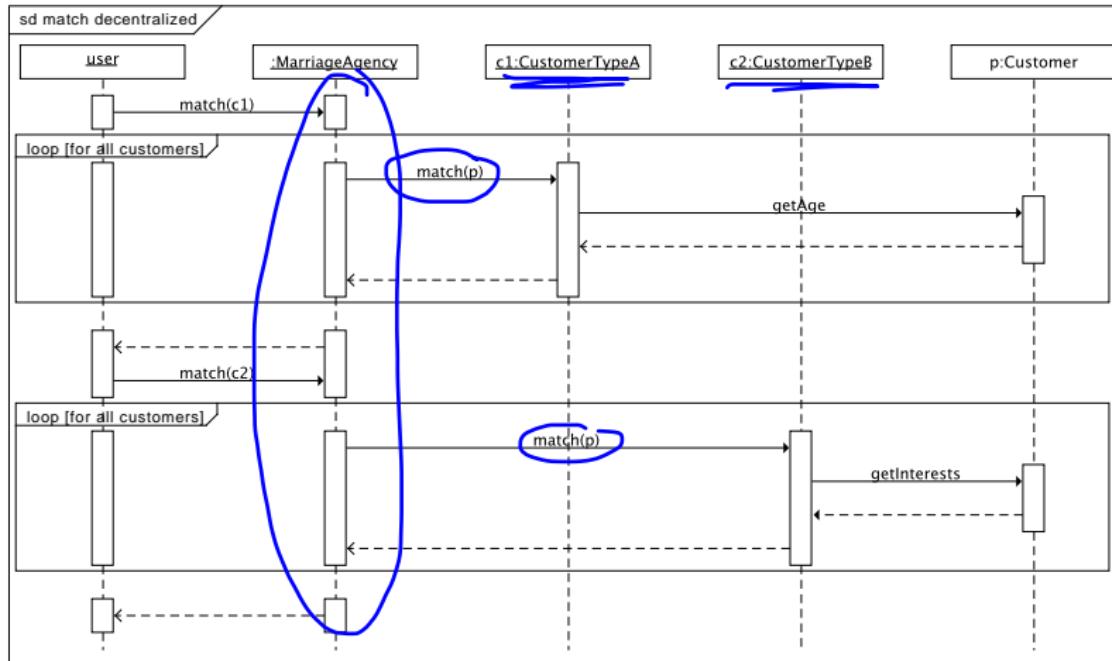

```
public List<Customer> matchCustomer(Customer c) {
    List<Customer> r = new ArrayList<Customer>();
    for (Customer p : customers) {
        if (c instanceof CustomerA) {
            if (matchCustomerTypeA(p)) { r.add(p); }
            continue;
        }
        if (c instanceof CustomerB) {
            if (matchCustomerTypeB(p)) { r.add(p); }
            continue;
        }
    }
    return r;
}
```

The code shows the implementation of the `matchCustomer` method. It iterates over a list of `customers`. For each customer `p`, it checks if it is an instance of `CustomerA` or `CustomerB`. If it is an `CustomerA`, it calls `matchCustomerTypeA(p)` and adds `p` to the result list `r` if true. If it is an `CustomerB`, it calls `matchCustomerTypeB(p)` and adds `p` to `r` if true. Red annotations highlight the condition `c instanceof CustomerA` and the method call `matchCustomerTypeA(p)`, indicating they are points of potential change.

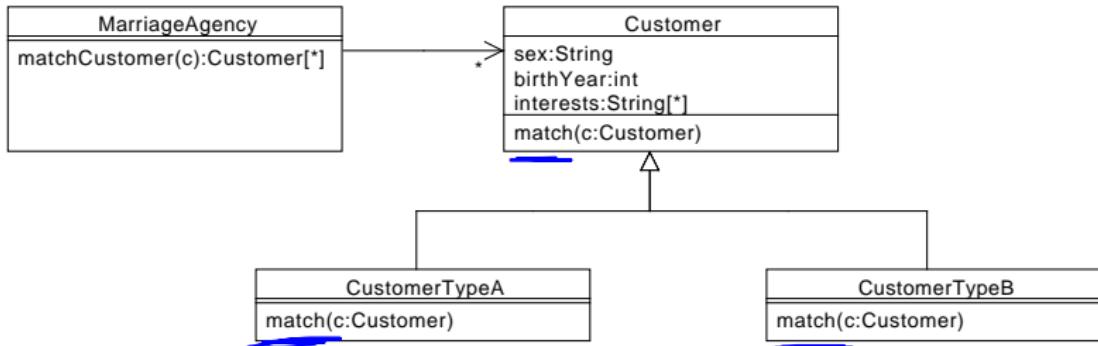

Design for change: centralized control

Design for change: decentralized control

Design for change: decentralized control

```
public List<Customer> matchCustomer(Customer c) {  
    List<Customer> matches = new ArrayList<Customer>();  
    for (Customer candidate : customers) {  
        if (c.match(candidate)) { matches.add(p); }  
    }  
    return matches;  
}
```

Sequence Diagrams II

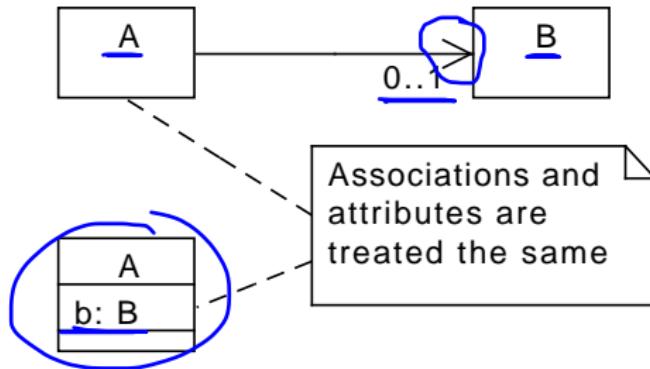

Object-orientation: Centralized vs Decentralized Control/Computation

Class Diagrams II

- Implementing Associations
- Bi-directional associations
- Associations

Layered Architecture

Implementing Associations: Cardinality 0..1

- ▶ Field can be null

```
public class A {  
    private B b;  
    public B getB() {  
        return b;  
    }  
    public void setB(B b) { this.b = b; }  
}
```

Implementing Associations: Cardinality 1

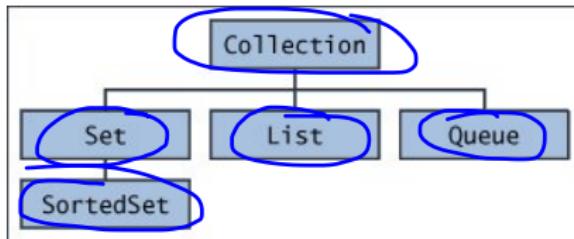

- ▶ Field may not be null

```
public class A {  
    2)    private B b = new B();  
    1)    public A(B b) { this.b = b; } → ↴ should not  
          public B getB() {  
              if (b == null) {b = computeB();}  
              return b;  
          }  
          public void setB(B b) { if (b != null) {this.b = b;} }  
    }
```

Interface *Collection<E>*

Operation	Description
<code>boolean <u>add(E e)</u></code>	returns false if e is in the collection
<code>boolean <u>remove(E e)</u></code>	returns true if e is in the collection
<code>boolean <u>contains(E e)</u></code>	returns true if e is in the collection
<code>Iterator<E> <u>iterator()</u></code>	allows to iterate over the collection
<code>int <u>size()</u></code>	number of elements

Implementing Associations: Cardinality *

Default: Unordered, no duplicates

```
public class A {  
    private Set<B> bs = new HashSet<B>();  
    ...  
}
```

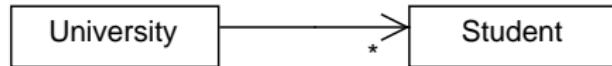

↑
interface ↑
 Impl. class
 →

encapsulation
implementation
hiding

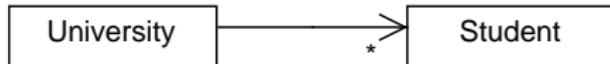

```
public class A {  
    private List<B> bs = new ArrayList<B>();  
    ...  
}
```

Encapsulation problem: getStudents

```
University dtu = new University("DTU");
..
Set<Student> students = dtu.getStudents();
```

Encapsulation problem: getStudents

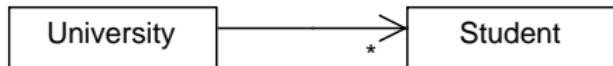

```
University dtu = new University("DTU");
..
Set<Student> students = dtu.getStudents(); ?
Student hans = new Student("Hans");
students.add(hans);
Student ole = dtu.findStudentNamed("Ole");
students.remove(ole);
..
```

Solution: getStudents returns an unmodifiable set

```
public void Set<Student> getStudents() {
    return Collections.unmodifiableSet(students);
}
```

Encapsulation problem: setStudents

```
University dtu = new University("DTU");
..
Set<Student> students = new HashSet<Student>();
dtu.setStudents(students);
```

Encapsulation problem: setStudents

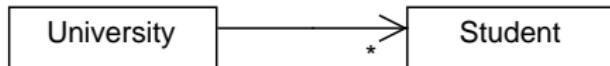

```
University dtu = new University("DTU");
...
Set<Student> students = new HashSet<Student>();
dtu.setStudents(students);

Student hans = new Student("Hans");
students.add(hans);
Student ole = dtu.findStudentNamed("Ole");
students.remove(ole);
...
```

Solution: setStudents copies the set

```
public void setStudents(Set<Student> stds) {
    students = new HashSet<Student>(stds);
}
```

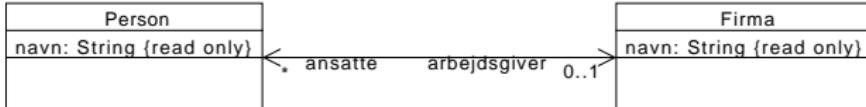

Solution: How to change the association?

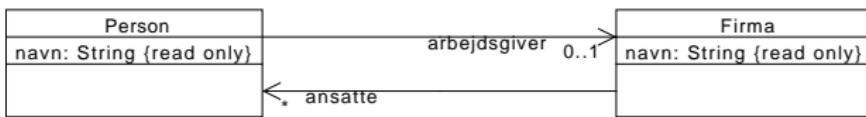

```
public class University {  
    private Set<Student> bs = new HashSet<Student>();  
  
    public void addStudent(Student s) {students.add(student);};  
    public void containsStudent(Student s) {return students.contains(s);}  
    public void removeStudent(Student s) {students.remove(s);}  
}
```

Even better: domain specific methods like *registerStudent*

Bi-directional associations

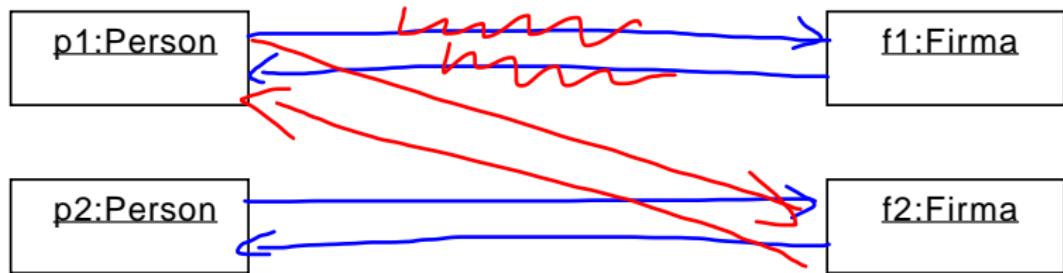

Implemented as two *uni-directional* associations

→ Problem of referential integrity

Referential Integrity

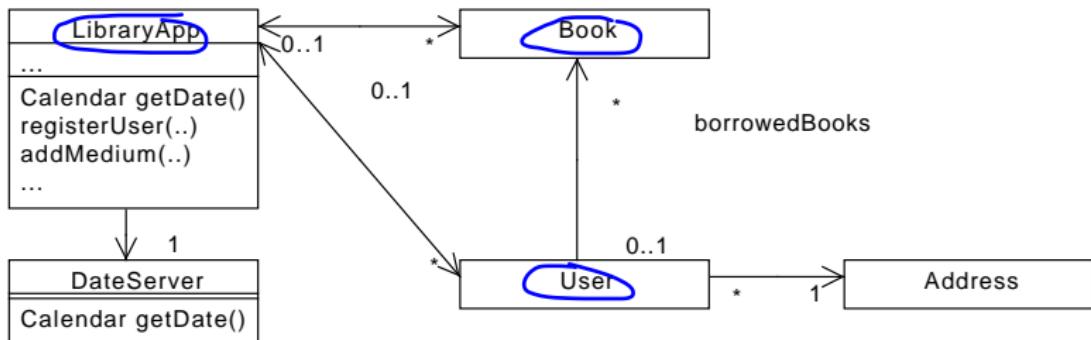

Referential Integrity: setArbejdsgiver

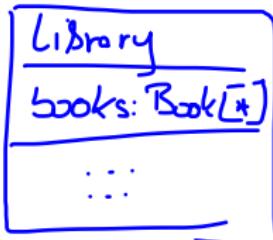

Referential Integrity: addAnsatte

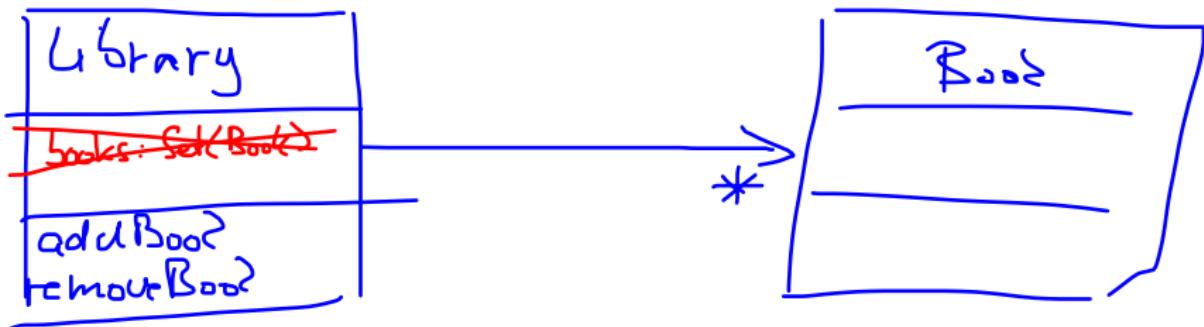

Library application

What is the class diagram for the following code?

```
public class Library {
    Set<Book> books = new HashSet<Book>();
    public void addBook(Book book) { ... }
    public void removeBook(Book book) { ... }
    ...
}
public class Book { ... }
```

Eric Evans, Domain Driven Design, Addison-Wesley, 2004

Example Vending Machine

Two different presentation layers; same application layer

- ▶ Swing GUI

- ▶ Command line interface

Current Money: DKK 5

- 0) Exit
- 1) Input 1 DKK
- 2) Input 2 DKK
- 3) Input 5 DKK
- 4) Select banana
- 5) Select apple
- 6) Cancel

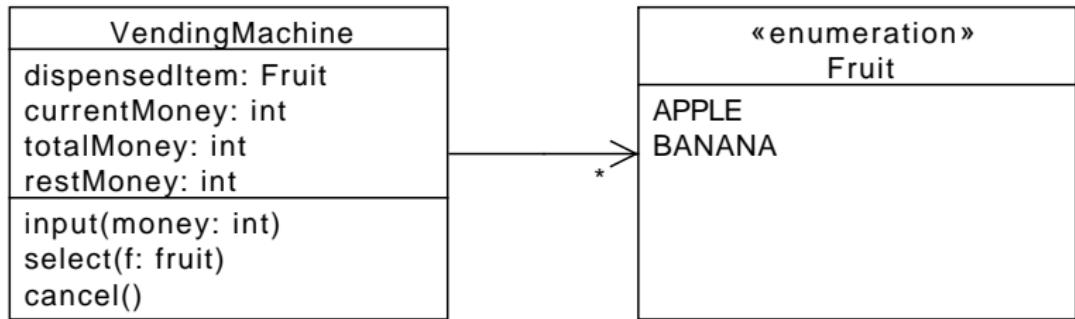

Select a number (0-6):

Rest: DKK 2

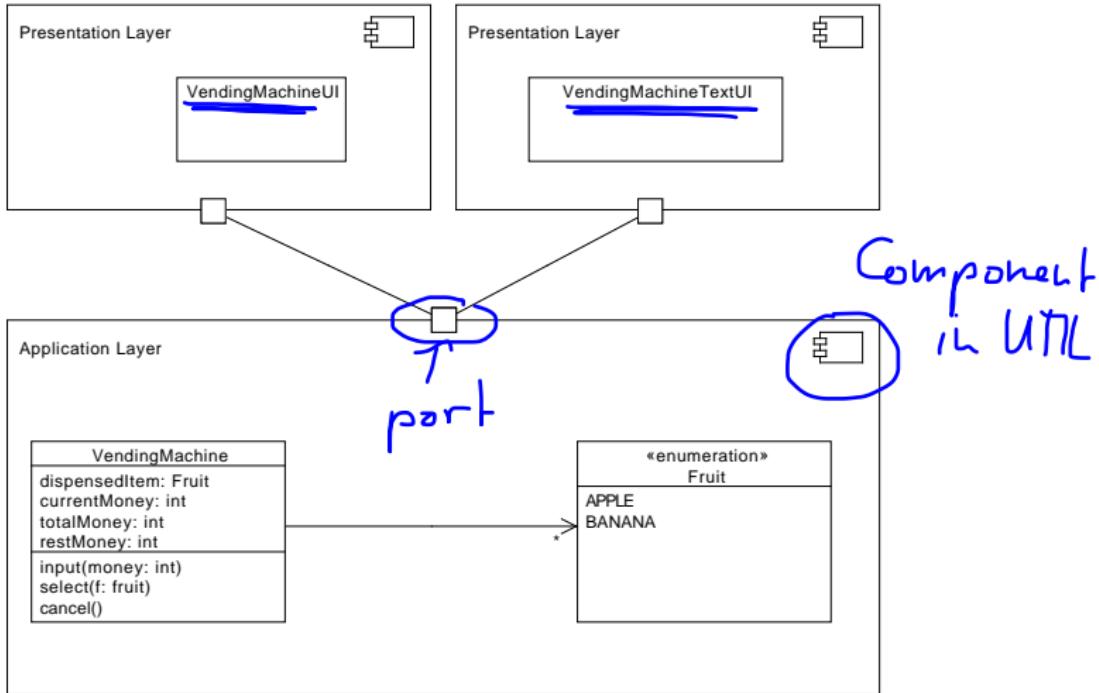

Current Money: DKK 0

Dispensing: Apple

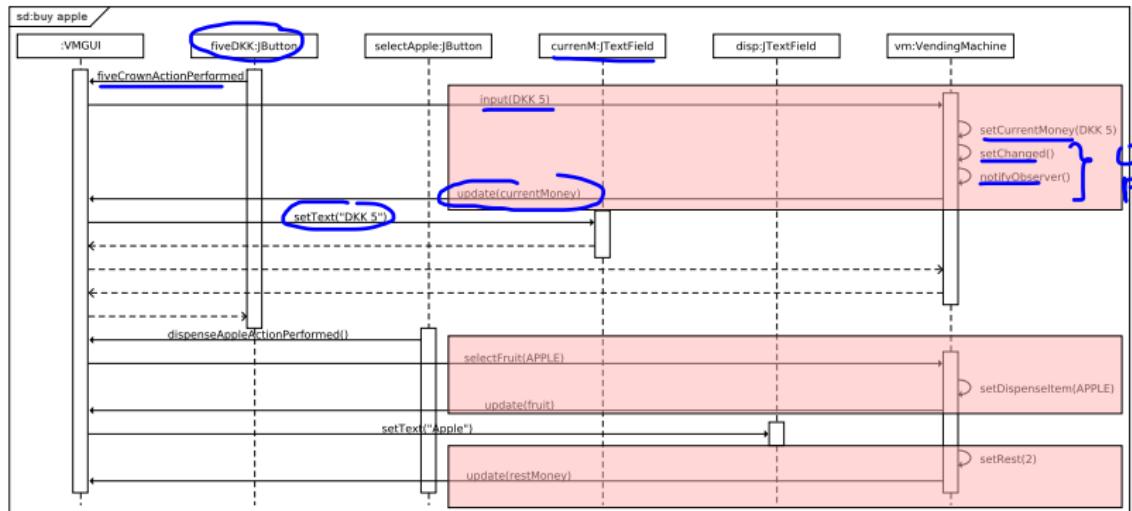

Application Layer

Architecture

Presentation Layer: Swing GUI

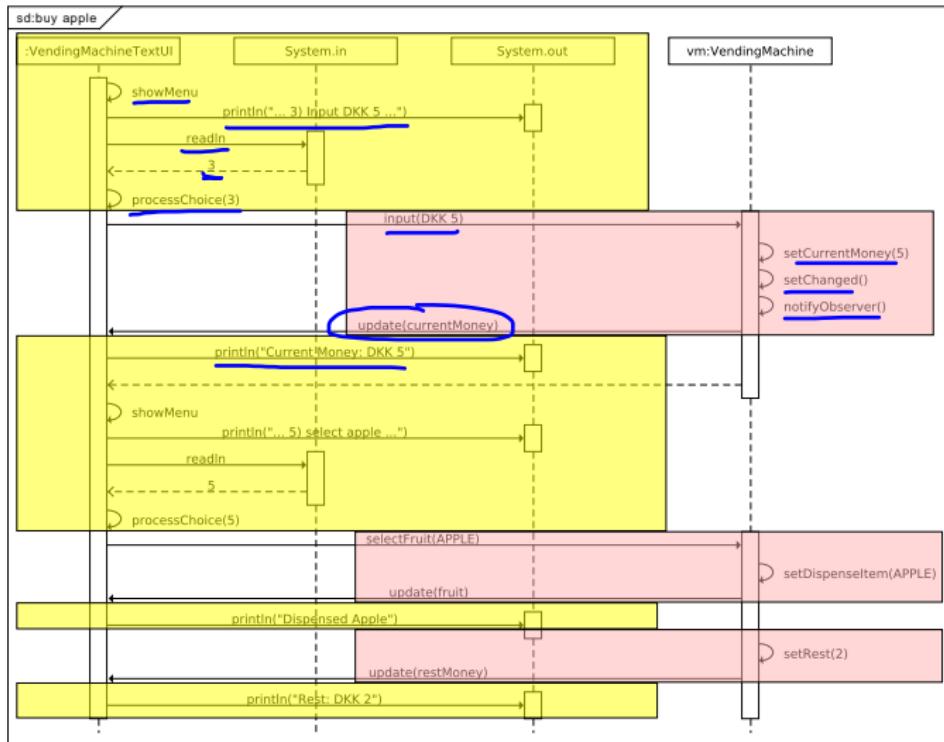

Presentation Layer: Swing GUI

```
public class VendingMachineUI extends javax.swing.JFrame
    implements java.util.Observer {
    private VendingMachine vendingMachine = new VendingMachine(10, 10);
    ...
    private JButton fiveCrowns = new JButton();
    private JTextField currentM = new JTextField();
    ...

    private void initComponents() {
        fiveCrowns.setText("DKK 5");
        fiveCrowns.addActionListener(new ActionListener() {
            public void actionPerformed(ActionEvent evt) {
                vendingMachine.input(5);
            }
        });
        ...
    };
    ...
    public void update(Observable o, Object arg) {
        currentM.setText("" + vendingMachine.getCurrentMoney());
        ...
    }
}
```

Presentation Layer: Command Line Interface

Presentation Layer: TextUI

```
public class VendingMachineTextUI implements Observer {  
    VendingMachine vendingMachine;  
    public static void main(String[] args) throws Exception {  
        new VendingMachineTextUI(5,5).mainLoop(System.in, System.out);  
    }  
    public void mainLoop(InputStream in, PrintStream out) throws IOException {  
        BufferedReader rs = new BufferedReader(new InputStreamReader(in));  
        do {  
            showMenu(out);  
            int number = Integer.valueOf(rs.readLine());  
            processChoice(number, out);  
        } while (number != 0);  
    }  
    private void processChoice(int number, PrintStream out) {  
        switch (number) {  
            case 3: vendingMachine.input(5); break;  
            ...  
        }  
    }  
    public void update(Observable o, Object arg) {  
        NotificationType type = (NotificationType) arg;  
        if (type == NotificationType.CURRENT_MONEY) {  
            System.out.println("Current Money: DKK " +  
                vendingMachine.getCurrentMoney());  
            return;  
        }  
    }  
}
```

Advantages of the separation

- 1 Presentation layer easily changed
- 2 Additional presentation layers can be added easily without having to reimplement the business logic
 - ▶ mobile app in addition to desktop and Web application
- 3 Automatic tests

```
public void testInputDataSetA() {  
    VendingMachine m = new VendingMachine(10, 10);  
    m.input(1);  
    m.input(2);  
    assertEquals(3, m.getCurrentMoney());  
    m.selectFruit(Fruit.APPLE);  
    assertEquals(Fruit.APPLE, m.getDispensedItem());  
}
```

- ▶ You should model the application and domain layer with your class diagrams and sequence diagrams
